AUTO TICKET CLASSIFICATION USING FLOW DESIGNER

Development Phase – Project Acceptance Test

Platform: ServiceNow **Project Type:** IT Helpdesk Automation

1. Project Acceptance Test Overview

The Project Acceptance Test (PAT) is conducted to verify that the developed Auto Ticket Classification solution meets the defined project requirements and behaves correctly in a ServiceNow IT helpdesk environment. The acceptance test focuses on whether incidents are automatically classified based on the information entered in the Short Description and Description fields.

The test also confirms that the Flow Designer automation is triggered correctly, classification rules are applied as expected, Category and Subcategory values are updated correctly, and the solution works consistently for common school or college IT helpdesk requests.

2. Acceptance Test Objectives

• Verify that the incident classification flow is configured and activated correctly.

• Confirm that relevant keywords in Short Description and Description are identified correctly.

• Verify automatic assignment of appropriate Category and Subcategory values.

• Confirm that the flow executes when an incident meets the defined conditions.

• Validate that unrelated or unclear incidents do not receive an incorrect classification.

• Verify that the final solution is usable, consistent, and ready for project demonstration.

3. Acceptance Criteria

No.	Acceptance Criterion	Expected Result
1	Incident creation	A new incident can be created successfully.
2	Keyword detection	Relevant keywords are identified from the configured incident fields.
3	Category assignment	Correct Category is automatically assigned.
4	Subcategory assignment	Correct Subcategory is automatically assigned where applicable.
5	Flow execution	Flow Designer runs when its trigger conditions are satisfied.
6	Unmatched ticket	Unclear/unmatched incidents remain unchanged or follow the default rule.
7	Data consistency	Classification values remain valid and consistent.
8	Usability	Helpdesk users can create incidents without additional manual classification steps.

4. Acceptance Test Scenarios

The following scenarios represent typical incidents expected in the project environment. Each scenario is tested by creating or updating an incident and checking the result after the Flow Designer automation executes.

Test ID	Scenario	Sample Input	Expected Classification	Acceptance Result
TC-01	Wi-Fi Issue	“Wi-Fi is not connecting”	Network / configured Wi-Fi subcategory	Category and Subcategory assigned correctly
TC-02	Projector Failure	“Classroom projector is not working”	Hardware / Projector	Correct hardware classification
TC-03	Password Problem	“Unable to reset my password”	Software / Password	Correct password-related classification
TC-04	Slow Computer	“Computer is running very slowly”	Hardware / configured computer subcategory	Correct computer-related classification
TC-05	Email Access	“Unable to access email”	Software / Email	Correct email classification
TC-06	Unrelated Request	“Need information about timetable”	No automatic classification / default	No incorrect IT classification

5. Detailed Acceptance Test Procedure

Step 1 – Create Test Incident: Open the ServiceNow incident form and enter a realistic helpdesk request in the Short Description and/or Description fields.

Step 2 – Submit or Update: Save the incident so that the configured Flow Designer trigger can evaluate the record.

Step 3 – Verify Flow Execution: Confirm that the flow is triggered according to the configured conditions and that no execution error is reported.

Step 4 – Verify Classification: Check the Category and Subcategory fields and compare the values with the expected classification for the test case.

Step 5 – Test Negative Case: Enter an incident that does not contain any configured classification keyword and verify that an incorrect category is not assigned.

Step 6 – Record Results: Mark each test case as Pass or Fail and record any observed issue for correction.

6. Test Data and Environment

Item	Acceptance Test Requirement
Application	ServiceNow
Module	Incident Management
Automation	Flow Designer
Input Fields	Short Description and Description
Output Fields	Category and Subcategory
Test Data	Wi-Fi, projector, password, slow computer, email and unmatched requests
Test Users	Authorized project/test users

7. Acceptance Test Result Evaluation

After executing the test scenarios, the project team reviews the results against the acceptance criteria. A test case is considered passed when the actual behavior matches the expected result without manual correction. Any failure is documented, corrected in the flow or classification rules, and tested again.

Result Status Definitions

Status	Meaning
PASS	Actual result matches the expected result and the acceptance criterion is satisfied.
FAIL	Actual result does not match the expected result and corrective action is required.
RETEST	The issue has been corrected and the same test case must be executed again.

8. Defect Handling and Retesting

• If a classification is incorrect, review the keyword/condition used by the flow.

• Verify that the Category and Subcategory choices are configured correctly.

• Check the Flow Designer trigger, conditions, actions, and update-record configuration.

• Correct the configuration and execute the failed test case again.

• Confirm that the correction does not negatively affect previously passed test cases.

9. Project Acceptance Checklist

✓	All major classification scenarios have been tested.
✓	Flow Designer trigger and actions work as configured.
✓	Category values are assigned correctly for supported incidents.
✓	Subcategory values are assigned correctly where applicable.
✓	Unmatched incidents do not receive an inappropriate classification.
✓	Test failures, if any, are corrected and retested.
✓	The solution is ready for final demonstration.
✓	Project documentation and acceptance results are recorded.

10. Final Acceptance Summary

The Project Acceptance Test validates that the Auto Ticket Classification using Flow Designer solution satisfies the planned functional requirements for an IT helpdesk environment. The test confirms that common incident requests can be processed automatically using predefined classification rules and that the appropriate Category and Subcategory values are applied through ServiceNow Flow Designer.

Successful completion of the acceptance test indicates that the developed solution is functionally ready for project demonstration and final documentation. The acceptance test results also provide evidence that the solution can reduce repetitive manual classification work and provide a consistent incident classification process.

Acceptance Decision: Accepted after successful completion of defined test cases and resolution/retesting of identified defects.
